**Description**

Ruby uses left-to-right evaluation order.

```ruby
def foo
  p :foo
  []
end
def bar
  p :bar
end
x, foo[0] = bar, 0
```

bar is foo, then :bar, then [] are evaluated.

```ruby
obj, obj.foo = obj.foo, obj
```

The swap is not performed.

IRC

foo[0] = bar

swap :foo :bar is not performed.

Evaluate multiple assignment left hand side before right hand side

In regular assignment, Ruby evaluates the left hand side before the right hand side. For example:

```ruby
foo[0] = bar
```

Calls foo, then bar, then [] on the result of foo.

Previously, multiple assignment didn't work this way. If you did:
Ruby would previously call bar, then baz, then abc, then def= on the result of abc, then foo, then []= on the result of foo.

This change makes multiple assignment similar to single assignment, changing the evaluation order of the above multiple assignment code to calling abc, then foo, then bar, then baz, then def= on the result of abc, then []= on the result of foo.

Implementing this is challenging with the stack-based virtual machine. We need to keep track of all of the left hand side attribute setter receivers and setter arguments, and then keep track of the stack level while handling the assignment processing, so we can issue the appropriate topn instructions to get the receiver. Here's an example of how the multiple assignment is executed, showing the stack and instructions:

```ruby
self                # putself
abc                # send
abc, self          # putself
abc, foo           # send
abc, foo, 0        # putobject 0
abc, foo, 0, [bar, baz] # evaluate RHS
abc, foo, 0, [bar, baz], baz, bar # expandarray
abc, foo, 0, [bar, baz], baz, bar, abc # topn 5
abc, foo, 0, [bar, baz], baz, abc, bar # swap
abc, foo, 0, [bar, baz], baz, def= # send
abc, foo, 0, [bar, baz], baz # pop
abc, foo, 0, [bar, baz], baz, foo # topn 3
abc, foo, 0, [bar, baz], baz, foo, 0 # topn 3
abc, foo, 0, [bar, baz], baz, foo, 0, baz # topn 2
abc, foo, 0, [bar, baz], baz, [bar, baz], baz # topn 1
[bar, baz], foo, 0, [bar, baz] # setn 3
[bar, baz], foo # pop
[bar, baz] # pop
```

As multiple assignment must deal with splats, post args, and any level of nesting, it gets quite a bit more complex than this in non-trivial cases. To handle this, struct masgn_state is added to keep track of the overall state of the mass assignment, which stores a linked list of struct masgn_attrasgn, one for each assigned attribute.

This adds a new optimization that replaces a topn 1/pop instruction combination with a single swap instruction for multiple assignment to non-aref attributes.

This new approach isn't compatible with one of the optimizations previously used, in the case where the multiple assignment return value was not needed, there was no lhs splat, and one of the left hand side used an attribute setter. This removes that optimization. Removing the optimization allowed for removing the POP_ELEMENT and adjust_stack functions.

This adds a benchmark to measure how much slower multiple assignment is with the correct evaluation order.

This benchmark shows:

- 4-9% decrease for attribute sets
- 14-23% decrease for array member sets
- Basically same speed for local variable sets

Importantly, it shows no significant difference between the popped (where return value of the multiple assignment is not needed) and !popped (where return value of the multiple assignment is needed) cases for attribute and array member sets. This indicates the previous optimization, which was dropped in the evaluation order fix and only affected the popped case, is not important to performance.

Cから受け継いだ代入の評価順が「おかしい」のが原因である(本来は a → b と表記すべきか) を考えると、むしろ foo[0] = bar が :bar, :fooと動作するようにすべきでしょうか。

いや、単なる思いつきなのですが。

ちなみに今調べたら mruby は foo[0] = bar が :bar, :fooと動作しますね。
Matz.

#9 - 04/10/2012 08:57 PM - mame (Yusuke Endoh)
まあ、それはそれでいいかなと思います。
ちなみに ISO とかの標準的にはどうなってるんでしょう？

1) 右辺が重複しないローカル変数の列だったら今まで通り
  副作用はないので問題ない
2) そうじゃなければ、色々コストをかけて順番通りに実行
  ということにしたいと思います。多分、(1) がほとんどではないかと期待。
  ネストした多重代入は、(1) にはあてはまりませんが、まぁしょうがない。

Evaluate multiple assignment left hand side before right hand side

In regular assignment, Ruby evaluates the left hand side before the right hand side. For example:

```ruby
foo[0] = bar
```

Calls foo, then bar, then `[]=` on the result of foo.

Previously, multiple assignment didn't work this way. If you did:

```ruby
abc.def, foo[0] = bar, baz
```

Ruby would previously call bar, then baz, then abc, then `def=` on the result of abc, then foo, then `[]=` on the result of foo.

This change makes multiple assignment similar to single assignment, changing the evaluation order of the above multiple assignment code to calling abc, then foo, then bar, then baz, then `def=` on the result of abc, then `[]=` on the result of foo.

Implementing this is challenging with the stack-based virtual machine. We need to keep track of all of the left hand side attribute setter receivers and setter arguments, and then keep track of the stack level while handling the assignment processing, so we can issue the appropriate `topn` instructions to get the receiver. Here's an example of how the multiple assignment is executed, showing the stack and instructions:

```
self             # putself
abc              # send
abc, self        # putself
abc, foo         # send
abc, foo, 0      # putobject 0
abc, foo, 0, [bar, baz] # evaluate RHS
abc, foo, 0, [bar, baz], baz, bar # expandarray
abc, foo, 0, [bar, baz], baz, bar, abc # topn 5
abc, foo, 0, [bar, baz], baz, abc, bar # swap
abc, foo, 0, [bar, baz], baz, def= # send
abc, foo, 0, [bar, baz], baz # pop
abc, foo, 0, [bar, baz], baz, foo # topn 3
abc, foo, 0, [bar, baz], baz, foo, 0 # topn 3
abc, foo, 0, [bar, baz], baz, foo, 0, baz # topn 2
abc, foo, 0, [bar, baz], baz, []= # send
abc, foo, 0, [bar, baz], baz # pop
abc, foo, 0, [bar, baz] # pop
[bar, baz], foo, 0, [bar, baz] # setn 3
[bar, baz], foo, 0 # pop
[bar, baz], foo # pop
[bar, baz] # pop
```

As multiple assignment must deal with splats, post args, and any level of nesting, it gets quite a bit more complex than this in non-trivial cases. To handle this, struct `masgn_state` is added to keep track of the overall state of the mass assignment, which stores a linked list of struct `masgn_attrasgn`, one for each assigned attribute.

This adds a new optimization that replaces a `topn 1/pop` instruction combination with a single `swap` instruction for multiple assignment to non-aref attributes.

This new approach isn't compatible with one of the optimizations previously used, in the case where the multiple assignment return value was not needed, there was no lhs splat, and one of the left hand side used an attribute setter. This removes that optimization. Removing the optimization allowed for removing the `POP_ELEMENT` and `adjust_stack` functions.

This adds a benchmark to measure how much slower multiple assignment is with the correct evaluation order.
This benchmark shows:

- 4-9% decrease for attribute sets
- 14-23% decrease for array member sets
- Basically same speed for local variable sets

Importantly, it shows no significant difference between the popped (where return value of the multiple assignment is not needed) and !popped (where return value of the multiple assignment is needed) cases for attribute and array member sets. This indicates the previous optimization, which was dropped in the evaluation order fix and only affected the popped case, is not important to performance.

Fixes [Bug #4443]

#22 - 05/05/2021 03:46 PM - Eregon (Benoit Daloze)
I wrote some concerns over this change in [https://bugs.ruby-lang.org/issues/15928#note-10](https://bugs.ruby-lang.org/issues/15928#note-10).
I think the previous semantics of multiple assignments are better for various reasons.
We could change single assignment order, always evaluate RHS first, like Mruby behaves, if consistency is wanted.
